A COMPARATIVE PHARMACOGNOSTIC EVALUATION OF ANATOMICAL AND CHEMICAL CHARACTERS OF *NARDOSTACHYS JATAMANSI* (D.DON) DC. (JATAMANSA) AND *VALERIANA MOONI* ARN. EX C.B.CLARKE (LANKA THUWARALA) Jayaratne R. K.^{1*}, Hettiarachchi P. L.² and Abeysekera A.³¹Bandaranaike Memorial Ayurvedic Research Institute, Nawinna, Maharagama. Sri Lanka.²Department of Biological Sciences, Faculty of Applied Sciences, Rajarata University of Sri Lanka, Mihintale, Sri Lanka.³Department of Chemistry, Faculty of Applied Science, University of Sri Jayawardenepura, Nugegoda, Sri Lanka.**Abstract**

Nardostachys jatamansi (Caprifoliaceae), known as Jatamansa, is an important plant in Ayurveda and traditional medicine in Sri Lanka. The dried rhizome of the plant is an important ingredient in many drugs. This plant does not grow in Sri Lanka. The practice has been to import it from India. However, currently its export has been banned as it has become an endangered species in India. An island wide market survey carried out by authors revealed, that the material sold as Jatamansa is substituted by materials other than its recommended substitute, *Valeriana wallichii* to an extent ranging from 66% to 100%. Substitution with materials other than recommended substitute might adversely affect the efficacy and safety of the drugs manufactured. As *V. wallichii* also does not grow naturally in Sri Lanka, the present study was carried out to compare pharmacognostic properties of *V. mooni* the only species of *Valeriana* found in Sri Lanka with *N. jatamansi* to evaluate the possibility of replacing *N. jatamansi* with *V. mooni* and to establish comparative quality standards of the two plant species which will enable to identify raw material at the point of purchasing.

Preliminary phytochemical screening indicated the presence of alkaloids, flavonoids and hydrolysable tannins in both species. The TLC analysis of the ethanol extract of the rhizomes, and GCMS analysis of their essential oils indicated that both species possess similar chemical compounds. The pharmacologically important principal sesquiterpene Jatamansone, was found even in higher amount in *V. mooni* (25.6%) than in *N. jatamansi* (8.9%). However clinical trials are needed to decide on the possibility of substituting Indian *N. jatamansi* with local *V. mooni*. The findings of the present study have added a new member to the potential list of medicinal plants and identified as an important endangered plant with the need for conservation, hence develop suitable propagation systems and cultivation.

Key words: *Valeriana mooni*, *Nardostachys jatamansi*, pharmacognosy, chemical analysis, jatamansone

1. Introduction

Herbal medicine is getting popular among people around the world. The use of accurate raw material is essential to produce high quality drugs with expected therapeutic values. With respect to quality control, correct identification of raw material in fresh, dry or powder state is of prime importance (Springfield et al., 2005). Misidentification and subsequent substitution with incorrect material might lead to severe health problems or even to death (Chaudhury & Rafei, 2002). Therefore, implementation of rigorous standardization procedure for raw material identification using botanical and chemical features will ensure high standards of the product with desired therapeutic values.

Nardostachys jatamansi of family Caprifoliaceae is an important medicinal herb in Ayurveda which is heavily used in Sri Lanka (Pandey, 1991), (Jadhav et al., 2009). This species is not recorded in Sri Lanka and importing of the material from India has been also banned since 1997 as it has become endangered in India. In Ayurveda practice, many exotics are being used mistakenly or as substitute when the original plant recommended does not grow in the country or when the amount of locally available raw materials is insufficient to meet the increasing daily demand. A survey carried out by authors among drug raw material dealers in five representative provinces and some Ayurveda and some traditional physicians in the country revealed that majority of them use subterranean part of a wild plant called *Balanophora fungosa* (Balanophoraceae) instead of *N. jatamansi*. This plant is not recommended as a substitute of *N. jatamansi* in any Ayurveda pharmacopeia. Therefore finding a possible substitutes for such rare and expensive raw material is vital therapeutically as well as economically.

Valeriana mooni (Caprifoliaceae) is an erect perennial critically endangered

herb, growing in high altitude areas of Sri Lanka and Tamil Nadu, India. Being globally threatened, *V. mooni* is an untouched medicinal plant. If *V. mooni* could be used as a substitute for *N. jatamansi*, it would minimize the unwanted bad effects which might be present in manufactured drugs due to the use of wrong raw material such as *Balanophora fungosa* (Balanophoraceae). However no reports are available regarding pharmacognostic properties of *V. mooni*. Even though *V. mooni* appears to be a safe substitute and possibly effective, it is not available in the market. Lack of investigations and documentation on pharmacognostic properties of *V. mooni* might be the reason for its unavailability in the crude drug market of the country. Therefore this species has hardly earned attention of conservationists and other researchers.

2. Material and Methods

2.1 Material

Raw, dried rhizomes of *V. mooni* collected from Pattipola herbal garden and market samples (dried rhizomes) of *N. jatamansi* were used in the present study. Collected samples were identified using their macro morphological and organoleptic characteristics, following standard methods (WHO, 1998). Then the identification was confirmed by comparing samples collected with the authenticated specimens deposited at drug museum of the Bandaranayake Ayurvedic Research Institute. Air dried plant materials were used for anatomical and chemical studies.

2.2 Microscopic studies

Microscopic studies (including powder microscopy) of raw material samples were carried out using standard methods (Trease & Evans, 1983; Prasad & Prasad, 1986 & Khandelwal, 2005).

2.2.1 Anatomical studies

Free hand sections of dried rhizomes of *N. jatamansi* and *V. mooni* soaked in water for ten minutes were taken using a sharp razor blade. Subsequently, sections were stained by double stained permanent slide method (Prasad & Prasad 1986). Anatomical features of the stained sections were studied using compound light microscope (model Kyowa, Biolux-12) and photomicrographs were taken (Sony cyber-shot digital camera).

2.2.2 Preparation of counter stained permanent slides of freehand sections

Selected sections were successively soaked in 30%, and 50% alcohol (for 5 minutes each) and subsequently stained with 1% safranin in 50% alcohol. Excess stain was washed off using 50% alcohol and subsequently, sections were dehydrated by treating successively with 70%, 90% alcohol (for 1 minute each), followed by 3 changes of absolute alcohol, keeping 1 minute interval at each step. Counterstaining was done using light green SF in clove oil for 2 minutes. Excessive stain was removed using absolute alcohol immediately. Sections were washed with clearing solution (clove oil) for 2 minutes. Clearing solution was removed by dipping sections for few minutes in xylene. After clearing in xylene for two changes, they were mounted on slides with a drop of Canada balsam (Prasad & Prasad 1986).

2.2.3 Powder Microscopy

Dried rhizomes were powdered using a grinder (Kinematica - CH-6014, Switzerland) and passed through steel sieve mesh No 355 (Retsch®, AS 200, Germany). Powder microscopic studies were carried out following standard method (Trease & Evans, 1983; Khandelwal, 2005). Small amount of powder of both plants were separately transferred to a drop of Chloral hydrate on cleaned glass slide. After mixing and placing a cover glass, the slide was

heated carefully over a small flame of micro burner until the air bubbles were completely removed. Ten microscopic fields (10x10 each) per sample were examined under compound light microscope and the relevant parameters were recorded. Photomicrographs of xylem components in the sample were taken using Sony cyber-shot digital camera.

2.3 Chemical Studies

2.3.1 Preliminary phytochemical screening

Qualitative chemical tests for identifying various phyto-constituents present were carried out following standard techniques (Trease & Evans 1983; WHO 1998; Khandelwal, 2005). Partially ground plant material (10 g) was kept in contact with 100 mL of 70% ethanol in a stoppered conical flask at room temperature for a period of 36 hours with frequent agitation (Tiwari *et al.*, 2011).

The extracts of plant materials prepared as above were subjected to a preliminary phytochemical analysis to detect the different chemical compounds present (Fong *et al.*, 1986).

2.3.2 Thin Layer Chromatography (TLC)

The powdered rhizome (20 g) was extracted sequentially with petroleum ether (60°-80 °C), ethyl acetate, and ethanol (80%) respectively in a Soxhlet apparatus (250 mL- YO-99036-50) for 6 hours. The ethanol extracts were evaporated in a rotary evaporator (Büchi® B-480 rotary evaporator) under reduced pressure at 40 °C. Resulted residue was stored in air tight dark containers at 4 °C until use.

Commercially available pre-coated (Merck) analytical high performance silica plates (Silica gel 60A, 20x20 cm, thickness of 0.25 mm) were used after prewashing them by eluting methanol once. Subsequently, plates were air dried and activated at 110 °C for 30 minutes prior to use. The samples were

applied to plates, and the plates were developed separately using petroleum ether (PE): ethyl acetate (EAc) 1:1; PE:EAc 4:1; EAc:Acetone 4:1 and dichloromethane (DCM) as solvent systems. The chromatograms were visualized under UV (366 nm) and by spraying with anisaldehyde sulphuric reagent.

2.3.3 Detection of valepotriates

The powdered rhizomes were extracted in a soxhlet apparatus using Dichloromethane. The sample was spotted on TLC plates and developed using toluene:ethyl acetate (3:1) as the mobile phase (Wagner *et al.*, 1984). Chromatograms were visualized by spraying with HCl – glacial acetic acid (GAA) reagent followed by heating at 110°C.

2.4 GCMS analysis

2.4.1 Extraction of oil using hydro distillation

Ground rhizomes were subjected to hydro-distillation using a Clevenger apparatus (3340024-Borosil®) for 6 hours. The heating was stopped and the volume of oil collected in the graduated tube was read after 10 min. The yield of the oil was calculated as milliliters per kilogram of drug (v/w). The total volume of oil and water containing any dissolved oil in the clevenger arm was extracted with hexane in a separating funnel. The hexane layer was dried over anhydrous sodium sulphate and evaporated in a rotary evaporator under vacuum at 40 °C and the last traces of hexane were removed by stream of nitrogen. The oil was stored at 4°C in

dark coloured air-tight containers and used within one week for Gas chromatography/ Mass spectrometry (GC/MS) analysis.

The oil (0.1 mL) was dissolved in 2 mL of hexane and 2 µL sample was injected to the GC/MS. The detected compounds were identified by comparing with National Institute of Standard and Technology (NIST), USA mass spectra data base and from retention times and mass spectra of standard compounds. The analysis of essential oils was carried out using GC/MS of Agilent Technologies, Model 7890A operating in the EI (Electron Impact) mode with an ionization energy of 70 eV equipped with a split injector. Helium used as a carrier gas at the flow rate of 0.8 mL/min, while HP – 5 MS (30 m x 0.25 mm, 0.25 µm) capillary column was used. The initial temperature was programmed at 40 °C at the rate of 5°C/min and 250 °C at the rate of 2 °C/min. The injector temperature was 275 °C.

3. Results

3.1 Macroscopic and organoleptic characteristics of two raw materials

Rhizomes of *V. mooni* (Figure 1a) are dull yellowish brown in color slightly curved unbranched, sub cylindrical, dorsiventrally somewhat flattened and marked with transverse ridges while those of *N. jatamansi* (Figure 1b) are externally reddish brown. Both are fibrous and have bitter taste with an aromatic smell.

Figure 1. Dried rhizomes of study plants : (a) *V. mooni*, (b) *N. jatamansi*

3.2 Anatomical and powder characteristics

In transverse section, the outer most tissue is made up of cork and it is specified as 4-7 layers of compact, radially elongated, rectangular to polygonal brownish cells in both species (Figure 2). Cortex is parenchymatous, moderately thick and secondary cortex (tissue just beneath the cork) consists of parenchyma cells with sinuous walls. Other part consists of parenchyma with moderately thick walls, numerous starch grains and oil globules (Figure 3).

Presence of inter xylary cork, stellate shaped medullary cork and schizogenous cavities is obvious in *N. jatamansi* (Figure 4) while they are absent in *V. mooni*. Collateral type 10-12 vascular bundles encircled by cork rings are prominent in *N. jatamansi* while

similar type of vascular bundles are organized in a ring in vascular region of *V. mooni* (Figure 5).

In both species, ray parenchyma are clear in some areas and phloem appears as patches of small cells. In *V. mooni* circular shape comparatively large pith remains alive with compact parenchymatous cells (Figure 6) while it becomes stellate shape, necrotic and is margined by medullary cork layer in *N. jatamansi* (Figure 5).

V. mooni is comparable with *N. jatamansi* in many powder characters. Both powders are yellowish brown, fibrous, aromatic and bitter in taste. Starch granules, sclerides and fibers are abundant in both species (Figures 7 and 8). Special features are summarized in Table 1.

3.3 Chemical Studies

3.3.1 Preliminary phytochemical screening

The results of the phytochemical screening of the two species are given in the Table 2.

The results for both plants were similar with positive results for alkaloids, flavonoids and hydrolysable tannins.

3.3.2 Thin layer chromatography

The sequential ethanol extract gave (under uv 366nm) a single fluorescent blue spot and $R_f = 0.42$ in both samples (Figure 9a) and an almost identical

pattern of purple gray spots ($R_f = 0.78, 0.67, 0.53, 0.33, 0.29, 0.22$) were found with anisaldehyde sulphuric acid reagent (Figure 9b).

When considering the TLC profiles which were used to determine the valepotriates in two plant species, both species exhibited four fluorescent bands at $R_f = 0.8, 0.7, 0.5$ and 0.3 under UV 366 nm and five common bands having $R_f = 0.82, 0.8, 0.65, 0.62, 0.37$ (pinkish brown) with HCL/GAA spray reagent (Figure 10).

As evident from the TLC finger prints, it could be suggested that the chemical constituents present in *V. mooni* and *N. jatamansi* are comparable.

Table 1. Characteristics of powdered dried rhizome of *V. mooni* and *N. jatamansi*

Character	<i>V. mooni</i>	<i>N. jatamansi</i>
Starch grains	Numerous, found in masses, mainly compound with,3, or 4 components	Numerous, simple or compound with 2,3,4 or occasionally up to 6 components
<i>Shape</i>	Spherical to ovoid	Sub spherical to polyhedral
<i>Diameter</i>	5-30 µm	2-30µm
<i>Hilum</i>	Rather indistinct small cleft or faintly visible radiate hilum	Fairly distinct radiate hilum or cleft with 3 -5 rays
<i>Striations</i>	Clearly visible	Clearly visible
Vessels	Singly or in small groups	Singly or in small groups
<i>Thickenings</i>	Annular Spiral	Scalariform Bordered Pitted Spiral
<i>Perforation</i>	Not detected	Circular simple
Tracheids	Found in groups of interlocking cells with annular thickenings	Rare
Sclerides	Common, found in groups	Common, found in small groups Isodiametric
<i>Shape</i>	Usually polyhedral	Evenly thickened, strongly striated, clearly visible
<i>Wall</i>	Heavily thickened, distinct striations, pits rarely found or undetectable	simple or branched pits
<i>Lumen</i>	Relatively broad and empty	Relatively broad and empty
<i>Size</i>	Vary	Vary
Fibers	Abundant, found scattered or associated with xylem	Abundant, found in groups or as isolated fragments
<i>Shape</i>	Moderately narrow with sharply pointed ends	Long ,narrow, frequently twisted, irregular in out line with blunt or pointed ends
<i>Walls</i>	Moderately thin with simple slit shaped pits	Partially lignified with few pits
<i>Lumen</i>	Relatively broad and empty , aseptate	Narrow, uneven, and often discontinuous, filled with contents , aseptate

3.3.3 Comparative analysis of the essential oils of two plant material

The oil extracted using hydrodistillation of the rhizomes exhibited a variation in their organolepticity (Table 3).

3.3.5 GCMS analysis

The oils, hydro distilled from the two plant materials were used for the GC/MS analysis.

Only a small number of peaks could be identified by comparing their mass spectrum with those in NIST library data bases (NIST 2011) suggesting that GC condition need to be optimized for better resolution. Table 4 gives the formulae, retention time (RT) and the relative concentrations (in percentage) of the compounds identified in GCMS analysis with a matching factor >90%.

The essential oils of both species are rich in sesquiterpenes. The main components detected in oil of *N. jatamansi* were patchouli alcohol

(16.66%), Jatamansone (8.9%), epialloaromadendrene (4.9%) and azulene (2.12%). Those in oil of *V. mooni* were Jatamansone (25.65%), 1H-Cyclopropa(a)naphthalene, decahydro-1,1,3a trimethyl -7- methylene- [1a.S-(1a- alpha,3a. alpha, 7 a beta, 7b, alpha (15.15%), γ -Gurjunene (8.81%) and Bornyl acetate (7.62%).

Further 1H-Cyclopropa(a)naphthalene, decahydro-1,1,3a trimethyl -7- methylene- [1a.S-(1a- alpha,3a. alpha, 7 a beta, 7b, alpha (15.15%), γ -gurjunene (8.81%) and Bornyl acetate (7.62%) were most abundant components among identified compounds in *V. mooni*. According to literature, most of these compounds are used in perfumery industry and possess sedative effects as in *N. jatamansi* (Long, 2000).

Table 3. Organoleptic properties and percentage yield of the essential oil of *V. mooni* and *N. jatamansi*

Property	<i>V. mooni</i>	<i>N. jatamansi</i>
Appearance	Fluid to slightly viscous liquid	Fluid to slightly viscous liquid
Colour	Pale yellow	Greenish blue
Aroma	Pleasant smell	Sweet woody and spicy-animal odor
* % of yield	0.47 $\pm$ 0.04	0.55 $\pm$ 0.11

*The values given are mean $\pm$ standard deviation (n=3, separate distillations)

4. Discussion

Results of the present study show that *N. jatamansi* and *V. mooni* which belong to the same family exhibit many similar features in their pharmacognostic characters. Therefore it could be suggested that there is a possibility of using *V. mooni* as a substitute for *N. jatamansi*.

In the TLC profiles, extracts of *N. jatamansi* and *V. mooni* indicated a close resemblance exhibiting similar bands in both species.

In GCMS analysis of *N. jatamansi* and *V. mooni* demonstrated a similarity in the chemical constitution and their essential oils. Both species had substantial quantities of Jatamansone, (*V. mooni* - 25.65%, *N. jatamansi*-8.93%) which has number of pharmacological actions, was recorded as the principal sesquiterpene and as the marker compound in jatamansa oil (Jha *et al.*, 2012). The presence of even a higher percentage (25.65% when compared to 8.93% in *N. jatamansi*) of this key compound in oil extracts of *V. mooni* provide evidence for its suitability to use as a substitute for *N. jatamansi*. In addition to Jatamansone, patchouli alcohol which is used in some drugs and also in perfumery industry was also detected in *N. jatamansi* (Long, 2000).

Moreover, macroscopic and microscopic characters (organoleptic, anatomical and powder microscopic characters) together with banding pattern in TLC of *N. jatamansi* and *V. mooni* presented in this study could be used in raw material identification at the time of purchase and this will minimize the risk of unintentional use of incorrect plant species in drug industry.

5. Conclusion

Phytochemical screening, TLC and GCMS analyses indicate that the chemistry of two species is similar but not identical. Therefore, it could be recommended that *V. mooni* be considered as a substitute for *N. jatamansi* with further clinical studies.

Moreover, *V. mooni* could be considered as a new addition to the list of medicinal plants in Sri Lanka. Findings of this study will support the possible medicinal usage of this plant which in turn will ensure that it will be propagated, cultivated and conserved. The data produced in the present investigation will also be helpful in the preparation of monograph of the herb for the inclusion in various pharmacopeias.
